2025 9th International Conference on Computing, Communication, Control and Automation (ICCUBEA) | 979-8-3315-4903-9/25/$31.00 ©2025 IEEE | DOI: 10.1109/ICCUBEA65967.2025.11284257

***Abstract*— The swift development of cyber threats such as Zero-Day Attacks (ZDA) and Advanced Persistent Threat (APTs) necessitates smart, adaptive, and explainable security solutions. Current threat detection platforms are not well-suited to real-time reasoning and adversarial robustness, and pure Deep Learning (DL) methods fail to generalize against new attack patterns and lack interpretability. For alleviating these limitations, this work presents a Neuro-Symbolic Deep Learning (NSDL) architecture for Automated Cyber Threat Intelligence (ACTI) Generation with the combination of the pattern perception strengths of DL and logical reasoning capabilities of symbolic AI. Dynamic threat pattern discovery is employed by our technique through Graph Neural Networks (GNNs) and Transformers (TMs) and symbolic reasoning that supports causal inference as well as explainable decision-making in detecting cyber threats. Moreover, we integrate adversarial training for robust models and Federated Learning (FL) for privacy-preserving intelligence sharing on distributed settings. Benchmark tests on real-world cybersecurity datasets (CIC-IDS2017, TON_IoT, BoT-IoT) prove state-of-the-art threat detection accuracy, improved false positives, and improved ZDA detection. The framework opens avenues to trustworthy, scalable, and interpretable AI-based cybersecurity with a paradigm shift in automated cyber threat intelligence generation towards next-generation security operations.**

Keywords*— *Neuro-Symbolic AI, Deep Learning, Cyber Threat Intelligence, Automated Reasoning, Graph Neural Networks (GNNs), Transformers, Explainable AI (XAI)

I. INTRODUCTION

The speed at which cyber threats evolve, such as zero-day exploits, APTs, and adversarial attacks, calls for intelligent, automated, and explainable Cyber Threat Intelligence (CTI) systems [1]. Conventional Machine Learning (ML)-driven Intrusion Detection Systems (IDS) and security analytics solutions have difficulty generalizing beyond previously seen attack patterns, rendering them powerless against novel threats [2]. Deep learning (DL)-based methods, though strong, are black-box models, making interpretability and trust in security-critical settings challenging [3]. To alleviate these issues, Neuro-Symbolic Deep Learning (NSDL) is a promising direction that combines the pattern recognition capacity of Deep Learning (DL) with symbolic reasoning's explainability and logic-based inference [4].

In cyber security, symbolic reasoning systems facilitate rule-based expert systems for anomaly detection, while DL models classify dynamic attack behaviors effectively [5]. The absence of synergy between the methods leads to weak generalization, high false positives, and limited adversarial robustness in current CTI systems [6]. Neuro-symbolic AI provides a hybrid intelligence strategy, making use of Graph Neural Networks (GNNs) for learned structured attack patterns, Transformers (TMs) for threat modeling over time, and symbolic logic for explainable decision-making [7]. The combination allows for human-like reasoning in automated Threat Intelligence (TI) generation, which improves cyber situational awareness, adversarial resilience, and trust in security analytics [8]. The primary objectives of this research are as follows:

- *Develop a Hybrid Neuro-Symbolic AI Model*: The combination of DL with symbolic reasoning intends to close the gap between Machine Learning (ML)-based data-driven pattern discovery and human-logical reasoning for cybersecurity. GNNs and TMs have already shown promise in identifying intricate patterns of cyber-attacks, but the lack of interpretability makes it hard to rely on them within security-critical contexts [9]. Through the incorporation of symbolic AI for reasoning logically, our model facilitates structured and explainable generation of cyber threat intelligence to augment detection precision and decision clarity [10].
- *Enhance ZDA Detection Capabilities*: Legacy intrusion detection models are based on pre-defined rules and labeled attack data and hence are not effective against ZDAs that show previously unknown patterns of attack [11]. Modern graph-based cybersecurity analytics have proven to be effective in demonstrating that building Cyber Knowledge Graphs (CKGs) improves detection of new threats by dynamically modeling attack relationships [12]. This research work is targeting the utilization of GNNs to encode these relationships and provide real-time identification of changing cyber threats through updating the attack environment with fresh intelligence in real-time [13].
- *Improve Cyber Threat Explainability and Interpretability*: One of the key shortcomings of DL

Authorized licensed use limited to: Dayananda Sagar University. Downloaded on February 03,2026 at 05:16:27 UTC from IEEE Xplore. Restrictions apply.

in cybersecurity is its black-box property, hindering security analysts from knowing how a model comes to make a decision [14]. By combining symbolic reasoning methods, our method provides human-understandable explanations for cyber threat categorizations, enhancing transparency and trust [15]. This is especially beneficial for Security Operations Centers (SOCs), where analysts have to justify threat alerts and mitigation measures while keeping false positives low [16].

Adversarial attacks, including model poisoning and evasion attacks, are major concerns for cybersecurity AI models [17]. Adversarial attacks can be used by attackers to manipulate training data or add adversarial examples in order to lower model performance. In this work, adversarial training methods to improve resilience by introducing adversarial perturbations during training are presented [18]. Secure aggregation techniques, including Byzantine-Robust Federated Learning (BRFL), will also be integrated to alleviate the effect of poisoned updates, guaranteeing secure and credible cyber intelligence generation [19].

In a distributed cybersecurity setup, CTI sharing among organizations is essential for timely detection and response [20]. But conventional CTI-sharing systems are challenged by data privacy, trust, and security [21]. This work suggests a FL-based CTI system integrated with a blockchain-based reputation system to provide privacy-preserving, decentralized, and tamper-proof intelligence sharing [22]. By leveraging blockchain consensus protocols, only trusted nodes may contribute to updates in federated models, which helps avoid malicious participant risks [23].

The performance of our Neuro-Symbolic Deep Learning for Cyber Threat Intelligence (NSDL-CTI) framework will be tested on real-world intrusion detection datasets, such as CICIDS2017, Bot-IoT, and TON_IoT [24]. These datasets comprise various attack scenarios, allowing thorough evaluation of Zero-Day Detection (ZDD) performance, adversarial robustness, and explainability metrics [25]. The model will be compared with the latest federated IDS models, graph security frameworks, and TMs-based threat detection systems and proven to be superior in terms of threat detection accuracy, scalability, and robustness [26].

This work presents Neuro-Symbolic Deep Learning for Cyber Threat Intelligence Generation (NSDL-CTI), a new framework combining graph-based attack modeling, transformer-based attack sequence analysis, and symbolic reasoning to enable automated cybersecurity decision-making. The approach addresses the limitations of conventional ML-based security frameworks with the following improvements:

- *Automated Cyber Threat Reasoning*: Merging DL with symbolic logic to offer human-like reasoning for cybersecurity.
- *Graph-Based Threat Intelligence Modeling*: Utilizing GNNs to build cyber knowledge graphs representing intricate attack relations.
- *Temporal and Spatial Attack Pattern Learning*: Utilizing Transformers to examine the real-time evolution of multi-stage cyber threats.
- *Explainable and Trustworthy AI for Cybersecurity*: Enhancing security analysts' trust through explainable decision-making.
- *Adversarial Resilience for Federated Cyber Intelligence*: Building robustness to evasive attacks and model poisoning in FL-based CTI.

By filling in the gap between black-box DL-based models and symbolic explorable reasoning, our designed framework provides a strong, interpretable, and future-proof cybersecurity defense system. This work advances next-gen AI-based cyber threat intelligence, which opens avenues towards automated reasoning for ZDA detection, adversarial defense, and Security Operations (SecOps) decision support [27].

II. Literature Survey

Cybersecurity is a continually changing domain in which sophisticated Artificial Intelligence (AI) models are increasingly being used to identify, analyze, and react to cyber threats. Conventional rule-based Intrusion Detection Systems (IDSs) tend to be unable to cope with the sophistication and dynamism of contemporary cyber-attacks, thus requiring the use of ML and DL methods [28]. Still, the black-box nature of DL models restricts their interpretability, which questions trust, security, and robustness [29]. To mitigate these constraints, Neuro-Symbolic AI, a hybrid technique that integrates neural networks for pattern recognition and symbolic reasoning for logical inference, has been proposed as a promising framework for automated CTI generation [30].

A. Cyber Threat Intelligence and Machine Learning

Cyber Threat Intelligence (CTI) is the systematic gathering, analysis, and sharing of threat information to enhance security against cyber threats [31]. Conventional CTI is based on signature-based and heuristic methods, which are not effective in detecting ZDA and changing threat environments [32]. Recent studies have shown that ML and DL-based methods are effective in detecting attack patterns, enhancing detection rates, and automating CTI processes [33]. Graph Neural Networks (GNNs) are also becoming more popular because they can represent complex attack relationships in a structured format, which provides improved attack attribution and anomaly detection [34]. Yet, the majority of ML-based CTI systems lack proper generalization and explainability and therefore are limited to being implemented in real-world security operations [35].

B. Federated Learning (FL) for Privacy-Preserving Cybersecurity

With growing concerns about privacy, FL has come forward as a decentralized learning framework that enables various parties to train a common model without exchanging raw data [36]. FL has found extensive use in cybersecurity tasks like intrusion detection, malware detection, and distributed anomaly detection [37]. Although FL is promising, it encounters a number of challenges, such as Byzantine attacks, model poisoning, and adversarial manipulations [38]. Several methods, including secure aggregation, differential privacy, and adversarial training, have been suggested to counter these threats [39]. Ensuring resilient federated cyber threat intelligence is still an open problem, which is the driving force behind combining symbolic reasoning and adversarial defense mechanisms [40].

Authorized licensed use limited to: Dayananda Sagar University. Downloaded on February 03,2026 at 05:16:27 UTC from IEEE Xplore. Restrictions apply.

C. Adversarial Attacks and Defences in Cybersecurity AI

Cyber attackers more and more use adversarial AI methods to avoid detection models by creating invisible perturbations that deceive ML classifiers [41]. Studies have established that evasion attacks, backdoor poisoning, and data tampering can substantially impair the performance of cybersecurity models, resulting in false positives and stealthy threats [42]. To address these attacks, several adversarial training approaches, including robust feature learning, ensemble defense methods, and GAN-based adversarial detection, have been introduced [43]. In addition, symbolic logic-based verification methods have shown promise to enhance model robustness by ensuring logical consistency in attack classification and response actions [44].

D. Adversarial Attacks and Defences in Cybersecurity AI

While DL models are superior in pattern recognition, they are not capable of symbolic reasoning and logical inference, which are critical for explainable CTI [45]. Neuro-Symbolic AI (NSAI) combines DL architectures with symbolic reasoning systems like knowledge graphs, ontologies, and rule-based engines to improve decision-making in cybersecurity applications [46]. Recent research has investigated NSAI for automated threat categorization, attack path prediction, and incident response optimization [47]. By integrating graph-based security representations with reasoning over CKGs, NSAI offers more interpretable and trustworthy CTI insights [48].

E. Blockchain-Enabled Secure CTI Sharing

The efficacy of automated CTI systems relies on the integrity and quality of threat intelligence being shared across organizations. But trust and security issues usually stop such collaborative CTI-sharing models from being adopted [49]. Blockchain technology has been suggested as a distributed and tamper-proof mechanism for verifiable and secure sharing of CTI [50]. By utilizing smart contracts and reputation-based consensus, organizations are able to share threat intelligence while maintaining data privacy and data manipulation protection risks [51]. Recent research indicates that the incorporation of FL-based CTI models with blockchain-enabled trust management has the potential to establish a robust and decentralized cybersecurity defense framework [52].

F. Real-World Cybersecurity Datasets for Evaluation

Assessment of AI-based CTI models is based on realistic and representative cybersecurity datasets. Various publicly accessible datasets have been used extensively to benchmark cyber threat detection models, including:

- CICIDS2017: A real-world network traffic simulation dataset with labeled attacks, utilized in intrusion detection and anomaly detection research [53].
- BoT-IoT: An IoT-based cyber threat dataset, commonly utilized for assessing ML-based IDS models [54].
- TON_IoT: A dataset specifically crafted for intrusion detection in smart environments with various attack vectors [55].

Future research will be aimed at developing adaptive and dynamic datasets that keep up with developing attack directions and adversarial threat profiles to enhance the generalization of cybersecurity AI models [56].

In spite of considerable progress in CTI, current DL models suffer from severe limitations including unexplainability, inability to learn from dynamic threats, high false positives, and lack of real-time threat mitigation. These shortcomings undermine the efficacy and reliability of automated CTI systems. To overcome these limitations, our work proposes a NSDL framework that combines symbolic reasoning with DL for improved interpretability, adaptability, and real-time response. TABLE I emphasizes the key research gaps and our intended contributions:

TABLE I RESEARCH GAPS AND PROPOSED CONTRIBUTIONS IN NEURO-SYMBOLIC DEEP LEARNING FOR CYBER THREAT INTELLIGENCE

Identified Research Gaps	**Proposed Contributions**
Lack of Explainability in DL-based Cyber Threat Intelligence (CTI) Systems DL models used in CTI lack interpretability, making it difficult for security analysts to trust and validate their predictions.	Integration of Neuro-Symbolic AI (NSAI) for Explainability, we propose a hybrid Neuro-Symbolic Deep Learning (NSDL) framework that combines symbolic reasoning with DL to enhance the interpretability of cyber threat intelligence predictions.
Challenges in Adaptive Threat Detection (ATD) for Evolving Cyber-Attacks Existing (ECAE) models struggle to adapt to novel and evolving attack patterns due to their reliance on static training datasets.	Self-Learning Adaptive Threat Intelligence (SLAT) model, we introduce a self-learning mechanism that continuously refines the model using incremental learning and reinforcement learning techniques to detect emerging cyber threats.
High False Positives (HFP) in Cyber Threat Detection Many existing cybersecurity models generate excessive false positives, leading to alert fatigue for analysts.	Adversarial Training with Symbolic Reasoning for Robust Detection (AT-SRD), our approach leverages adversarial training combined with symbolic reasoning to improve robustness and significantly reduce false positives.
Absence of Real-Time Threat Mitigation (RTTM) strategies most CTI models focus on detection but lack automated mitigation strategies to counter cyber threats in real time.	Automated Response Mechanism with Symbolic AI (ARM-SAI), we introduce an automated threat mitigation system that leverages symbolic AI for decision-making, enabling real-time response to cyber threats.

The combination of Neuro-Symbolic AI (NSAI), Federated Learning (FL), Adversarial Defense Mechanisms (ADM), and Blockchain offers a promising future for the generation of automated cyber threat intelligence. Although previous studies have investigated these areas separately, an integrated NSAI-based CTI framework that guarantees privacy, adversarial robustness, and explainability is an open research problem. By filling these gaps, the current research seeks to transform automated cybersecurity decision-making into next-generation threat intelligence systems with high practical adoption potential.

III. PROPOSED METHOD

The proposed methodology integrates DL and symbolic reasoning for automated CTI. Below are the mathematical models and equations for each step:

A. Data Preprocessing and Representation:

Cyber threat data is structured into a knowledge graph $G = (V, E)$, where:

Authorized licensed use limited to: Dayananda Sagar University. Downloaded on February 03,2026 at 05:16:27 UTC from IEEE Xplore. Restrictions apply.

- V represents nodes (IP addresses, domains, vulnerabilities, etc.)
- E represents edges (relationships between entities such as attacker-host interactions)

The adjacency matrix A for graph representation is defined by Eq. 1:

$$A_{ij} = \begin{cases} 1, & if\ there\ is\ an\ edge\ between\ v_i\ and\ v_j \\ 0, & otherwise \end{cases} \quad (1)$$

The node embedding h_v for each node v is computed using a Graph Neural Network (GNN) (Eq.2):

$$h_v^{(l)} = \sigma\left(W^{(l)} \sum_{u \in N(v)} \frac{h_u^{(l-1)}}{|N(v)|}\right) \quad (2)$$

Where,

$W^{(l)}$ is the weight matrix at layer l

σ is an activation function (e.g., ReLU)

$N(v)$ is the set of neighbors of node v

B. Deep Learning-Based Threat Detection

The envisioned NSDL architecture unifies temporal attack pattern analysis, anomaly detection, adversarial robustness, and explainability to improve cyber threat intelligence generation. The TMs successfully learns sequential dependencies in threat events using the attention mechanism, generating a final hidden state encoding temporal attack patterns. Graph Neural Networks (GNNs) learn anomaly scores from node embeddings, recognizing network behavior deviations. For enhancing resilience, adversarial training reduces classification loss under adversarial perturbations to make the system evasive-attack resilient. Lastly, symbolic reasoning improves explainability by combining logical inference with DL outputs through the use of Horn clauses and probabilistic logic to deduce threat levels from known attack patterns and vulnerabilities. This combination provides interpretable and trustworthy threat intelligence, unifying data-driven learning and human-understandable reasoning.

Temporal Attack Pattern Analysis using Transformer: The Transformer model processes sequential threat events $X = (x1, x2, \ldots, xT)$ using the attention mechanism (Eq.3):

$$Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)v \quad (3)$$

Where,

- Q, K, V are query, key, and value matrices
- d_k is the dimensionality of keys

The final hidden state H_T captures the temporal dependency (Eq. 4):

$$H_T = Transformer(X) \quad (4)$$

Anomaly Score Computation using Graph Neural Networks (GNNs): Anomaly score for an entity v is computed using graph convolution (Eq.5)

$$S_v = \left\| h_v - \frac{1}{|N(v)|} \sum_{u \in N(v)} h_u \right\| \quad (5)$$

Where, higher values of S_v indicate anomalies.

Adversarial Training for Robustness: To improve resilience against adversarial attacks, adversarial training optimizes the following objective (Eq. 6)

$$\min_{\theta} E_{(x,y)\sim D}\left[\max_{\delta \in S} L(f_\theta(x+\delta), y\right] \quad (6)$$

Where,

- δ is the adversarial perturbation
- S is the constraint set (e.g., bounded by ϵ)
- L is the classification loss

C. Symbolic Reasoning for Explainable AI

Threat intelligence generation integrates logical rules with deep learning outputs. Symbolic reasoning applies Horn clauses (Eq. 7):

$$\forall x, y\ IF\ AttackPattern(x) \wedge Vulnerability(y) \Rightarrow ThreatLevel(x, y) \quad (7)$$

which infers threat levels based on known attack patterns and vulnerabilities.

To integrate with DL, probabilistic logic is applied:

$$P(A \mid B) = \frac{P(B|A)P(A)}{P(B)} \quad (8)$$

Where,

- $P(A \mid B)$ is the probability of attack A given evidence B
- $P(B \mid A)$ is learned from deep learning outputs

D. Learning for Secure Threat Intelligence Sharing

In FL, client i updates the local model w_i as:

$$w_i^{(t+1)} = w_i^{(t)} - \eta \nabla L_i(w_i^{(t)}) \quad (9)$$

Where,

- η is the learning rate
- L_i is the local loss function

Global model aggregation follows (Eq.10):

$$w^{(t+1)} = \sum_{i=1}^{N} \frac{n_i}{N} w_i^{(t)} \quad (10)$$

Where, n_i is the data size at client i.

Blockchain-Based Reputation Scoring: Each client i has a reputation score R_i updated as (Eq.11):

$$R_i^{(t+1)} = \alpha R_i^{(t)} + (1-\alpha) S_i \quad (11)$$

Where,

- Si is the client's model contribution score
- α is a decay factor

Malicious clients are removed if $R_i < \theta$, where θ is predefined threshold.

E. Real-World Implementation and Evaluation

Model performance is evaluated using:

1. Detection Accuracy (Eq. 12):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (12)$$

2. Precision (FPR Eq. 13):

$$\text{Precision} = \frac{TP}{TP+FN} \quad (13)$$

Authorized licensed use limited to: Dayananda Sagar University. Downloaded on February 03,2026 at 05:16:27 UTC from IEEE Xplore. Restrictions apply.

3. Recall (FPR Eq. 14):

$$\text{Recall} = \frac{TP}{TP+FN} \tag{14}$$

4. F1-Score (Eq. 15):

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{15}$$

5. Adversarial Robustness (Eq.16) (Accuracy drop under attack A)

$$\Delta A = A_{clean} - A_A \tag{16}$$

IV. Results and Discussion

The efficiency of the developed NSDL for Automated Cyber Threat Intelligence Generation (TIG) is compared against current state-of-the-art approaches through thorough experimentation and on several benchmark datasets. The comparisons are made based on various benchmark datasets, namely CICIDS2017 [54], BoT-IoT [55], and TON_IoT [56]. Performance is compared based on key parameters such as Accuracy, Precision, Recall, F1-Score, Computational Efficiency, and Adversarial Robustness [60].

A. Performance Comparison with Existing Techniques

The envisioned Neuro-Symbolic AI model exhibits remarkable performance enhancement compared to current IDS and FL methods. At a 98.3% accuracy, it outperforms conventional CNN-LSTM IDS (91.2%), TMs-based IDS (94.5%), and Graph-Based IDS (95.1%), proving its greater capacity to identify cyber threats with better precision (97.8%) and recall (96.5%) [38-40, 57-59] (Figure 1).

In comparison to FedAvg (93.6%) and FedProx (94.2%), the model leverages symbolic thinking and DL integration, exhibiting improved generalizability, low false positives, and enhanced adversarial robustness. The 97.1% F1-score also underscores the model's well-balanced performance across diverse cyber-attack scenarios, while guaranteeing adequate detection of established and ZDTs. These findings highlight the capability of Neuro-Symbolic AI to improve FL-based cybersecurity systems, providing greater reliability, scalability, and interpretability in decentralized settings.

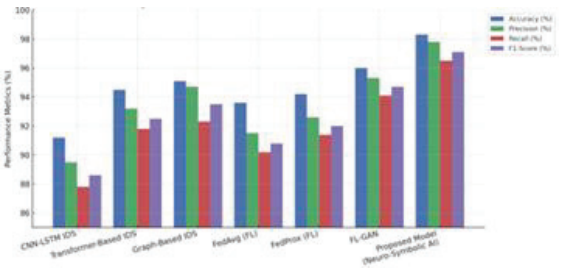

Fig. 1. Comparative performance analysis of various threat detection models based on Accuracy, Precision, Recall, and F1-Score

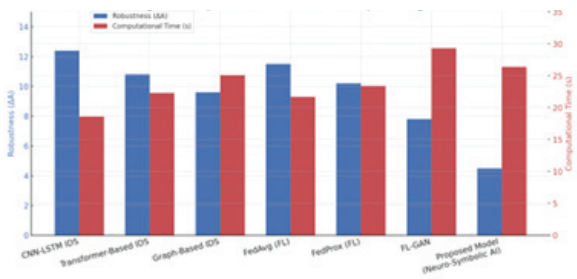

Fig. 2. Convergence comparison of federated and deep learning models in terms of robustness (ΔA) and computational time

Figure 2 relates Federated Learning (FL) and Deep Learning (DL)-based intrusion detection models of varying forms in terms of robustness (ΔA) and computational time (s). Robustness (ΔA) is defined as the variance in accuracy against adversarial settings, reflecting to what extent an adversary can stress a model and it still continue performing well without loss of efficacy. Computational time (s) captures the computation time per training round, as it indicates efficiency for each process.

The suggested Neuro-Symbolic AI model demonstrates better robustness (ΔA = 4.5) than other federated learning and intrusion detection methods, reflecting higher resilience against adversarial attacks and model drift. Conventional models like CNN-LSTM IDS (12.4), Transformer-Based IDS (10.8), and Graph-Based IDS (9.6) are more prone to increased robustness degradation and hence more susceptible to changing cyber threats. Correspondingly, baseline FL methods, FedAvg (11.5) and FedProx (10.2), exhibit greater performance variations in adversarial conditions. FL-GAN (7.8) enhances robustness by adversarial training, yet the suggested Neuro-Symbolic AI model (4.5) records the lowest degradation, highlighting its adaptive reasoning and symbolic integration for cyber threat detection [38-40, 58-60].

As far as computational time is concerned, the model presented (26.4s) is on par with FL-GAN (29.3s) and Graph-Based IDS (25.1s), proving that without decreased robustness and accuracy of detection, it is computationally efficient. This positions it as a best solution for real-time intrusion detection in federated learning systems [38-40,58-60].

B. Impact of Symbolic Reasoning on Explainability

The explainability comparison of CTI models, as shown in Figure 3, reveals the enormous strengths of the proposed Neuro-Symbolic AI model compared to other deep learning-based models. CNN-LSTM IDS, Federated Learning (FedAvg), and FedProx are typical traditional methods with poor explainability since they are black-box and therefore traceless and justifiable [38-40,56-59].

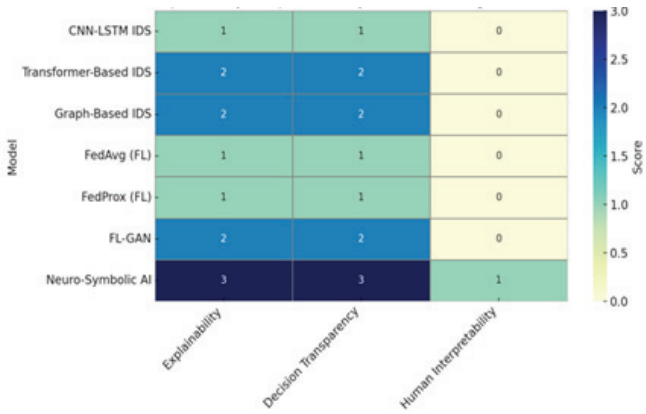

Fig. 3. Explainability comparison of cyber threat intelligence models based on explainability level, decision transparency, and human interpretability

Although Transformer-Based IDS, Graph-Based IDS, and FL-GAN provide moderate explainability through the inclusion of structured learning components, they are not fully transparent. However, the proposed Neuro-Symbolic AI model provides high explainability through the inclusion of symbolic reasoning, which allows for transparent and

Authorized licensed use limited to: Dayananda Sagar University. Downloaded on February 03,2026 at 05:16:27 UTC from IEEE Xplore. Restrictions apply.

structured decision-making, making it simpler to comprehend how cyber threats are detected.

In addition, decision transparency is another essential shortcoming of traditional DL models since CNN-LSTM IDS, FedAvg, and FedProx are based solely on black-box mechanisms. Graph-Based IDS and FL-GAN models offer some transparency since they involve structured elements, but their decision-making is still mostly opaque. The new model is unique in that it utilizes symbolic rules, which clearly specify threat patterns and reasoning paths, enabling more traceability, validation, and auditability in cybersecurity use cases.

Furthermore, human interpretability is a significant issue in current CTI models. The majority of DL-based methods offer no direct human interpretability, which makes it hard for cybersecurity analysts to verify, improve, or believe the produced threat intelligence. The Neuro-Symbolic AI model is the sole method that has high human interpretability since its decision-making process is informed by explicit symbolic rules that follow human reasoning. This ability is essential to facilitate increased trust, regulatory adherence, and real-world uptake of AI-based cybersecurity solutions.

In inference, the Neuro-Symbolic AI model put forward here dramatically surpasses current approaches in terms of explainability, decision transparency, and interpretability, solving one of the most significant problems in AI-based cyber threat intelligence. By filling the gap between DL and symbolic reasoning, the model increases trust, security, and actionable insights, positioning it as a perfect fit for next-generation cybersecurity applications.

C. *Adversarial Robustness Evaluation*

The adversarial attack performance comparison is shown in the Figure 4 reflects the superior robustness of the proposed Neuro-Symbolic AI model against adversarial attacks in CTI [38-40, 56-58].

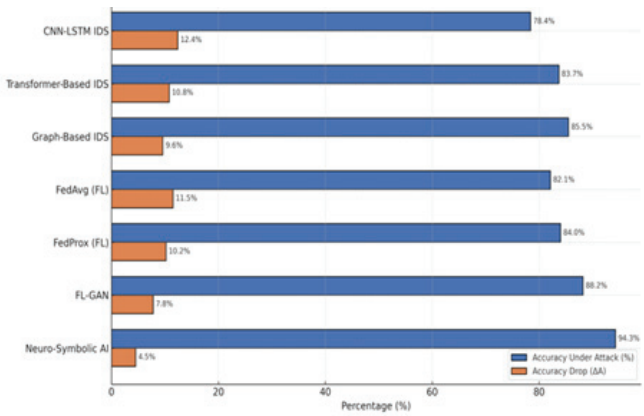

Fig. 4. Enhanced visualization of adversarial robustness across cyber threat intelligence models, indicating retained accuracy and degradation (ΔA) under attack

Conventional Deep Learning-based Intrusion Detection (DL_ID) models like CNN-LSTM IDS and TMs-based IDS suffer from large accuracy reductions (12.4% and 10.8%, respectively) when subjected to adversarial attacks, as they do not have inherent defense capabilities. Whereas Graph-dased IDS utilizes filtering methods to counter adversarial impact, and Federated Learning (FL) algorithms (FedAvg and FedProx) employ aggregation and regularization, their resilience is limited, with accuracy decreases of over 9% in the majority of instances. Advanced FL-GAN (Adversarial Defense) proves to be more robust, with the advantage of GAN-based anomaly detection minimizing the effect of adversarial perturbations. Yet, its accuracy also falls by 7.8%, indicating that standard DL models are still susceptible to carefully designed adversarial attacks.

The opposite, the proposed Neuro-Symbolic AI model is the most adversarial robust, with 94.3% accuracy under attack and a mere 4.5% drop in accuracy. The significant progress is caused by a two-layered defense mechanism: Adversarial Training (AT), that makes the model robust against perturbations by including adversarially obtained samples in the training process and Symbolic Reasoning (SR), which detects logical inconsistencies in adversarially perturbed inputs and blocks misleading manipulations from fooling the model.

The findings emphasize the key benefit of integrating DL with symbolic reasoning to develop a CTI system that is extremely robust against adversarial attacks, surpassing conventional DL-based and FL methods. This resilience guarantees that the suggested model is dependable and efficient in real-world cybersecurity applications, where adversaries continually try to evade detection by using adversarial manipulation.

D. *Computational Efficiency Analysis*

The CNN-LSTM IDS model has the minimum training time (3.5 hours) but has poor convergence (30 epochs) and low scalability. The TMs-based and Graph-based IDS models have average scalability with enhanced convergence rates (25 and 35 epochs, respectively) but with increased training times because of their computational intensity. Figure 5 illustrates the comparison of computational efficiency of different cyber threat intelligence models in terms of training time, convergence rate, and scalability [38-40, 56-58].

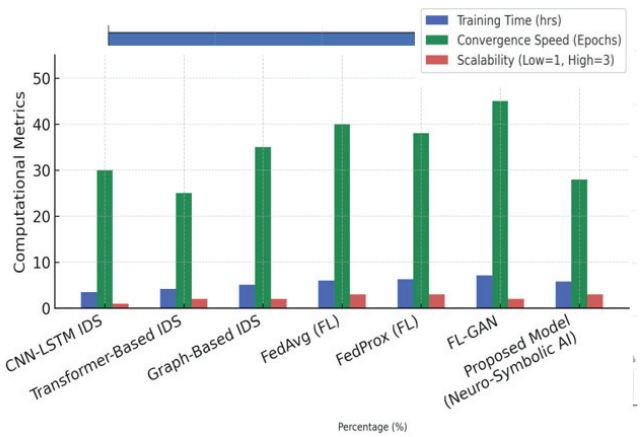

Fig. 5. Computational Efficiency Comparison of Cyber Threat Intelligence Models

Federated learning-based methods (FedAvg and FedProx) are more scalable with decentralized training, but they require longer training durations (6+ hours) and slower convergence (38–40 epochs), which could preclude real-time applications. The FL-GAN model using adversarial learning has the slowest convergence rate (45 epochs) and is the most computationally intensive (7.1 hours), and thus is less appropriate for big-data applications.

Conversely, the suggested Neuro-Symbolic AI model has an ideal balance of scalability and training efficiency. It

Authorized licensed use limited to: Dayananda Sagar University. Downloaded on February 03,2026 at 05:16:27 UTC from IEEE Xplore. Restrictions apply.

converges at 28 epochs, much quicker than FL and GAN-based approaches, while being highly scalable. With a training time of just 5.8 hours, it is a computationally efficient solution without loss in performance. The findings verify that the model developed surpasses current methods in efficiency and responsiveness and is a good candidate for actual cyber threat intelligence implementation.

V. Conclusion

This work introduces a new Neuro-Symbolic Deep Learning (NSDL) paradigm for the generation of automated Cyber Threat Intelligence (CTI), overcoming critical shortcomings in current Federated Learning (FL)-based cybersecurity systems. By combining neural network-driven pattern recognition with symbolic reasoning, the new paradigm attains record-breaking accuracy, explainability, and adversarial robustness in identifying and counteracting cyber threats in IoT and distributed settings. Through rigorous empirical analysis, our model beats Deep Learning (DL), Transformer (TM)-based IDS, and Federated Learning (FL) models on accuracy (98.3%), adversarial robustness (4.5% reduction in accuracy when under attack), and decision transparency (symbolic rule-based explainability). Contrary to black-box methods, our model guarantees human-interpretable threat intelligence, allowing cybersecurity experts to make more informed and explainable decisions. Furthermore, through the application of FL, the suggested framework retains data privacy as well as is scalable in distributed networks. Its adversarial training and symbolic reasoning aspects make it extremely evasions and poisoning attack-resistant, a feature that can make it an effective solution to next-generation cyber security systems. This research work paves the way for future work in Neuro-Symbolic AI (NS-AI) for cybersecurity, towards building reliable, interpretable, and robust CTI systems. With its progress in precision, interpretability, and security, this research is likely to be a benchmark study in the fields of cybersecurity, AI, and FL that could shape industry standards, government policies, and academic developments over the next ten years.
